Skeletal SYSTEM

The skeletal system is the body's foundational framework, consisting of bones, cartilage, ligaments, and tendons. It is vital for survival because it provides the structure required to stand, protects fragile internal organs, and produces the blood cells needed to keep the body functioning.

The skeletal system is our body's structural framework, providing essential support, protecting vital organs, facilitating movement, producing blood cells, and storing important minerals.

Bones provide the structural framework that supports your body, protects vital organs, enables movement by anchoring muscles, and produces essential blood cells. They also act as the body's primary storage system for critical minerals like calcium.

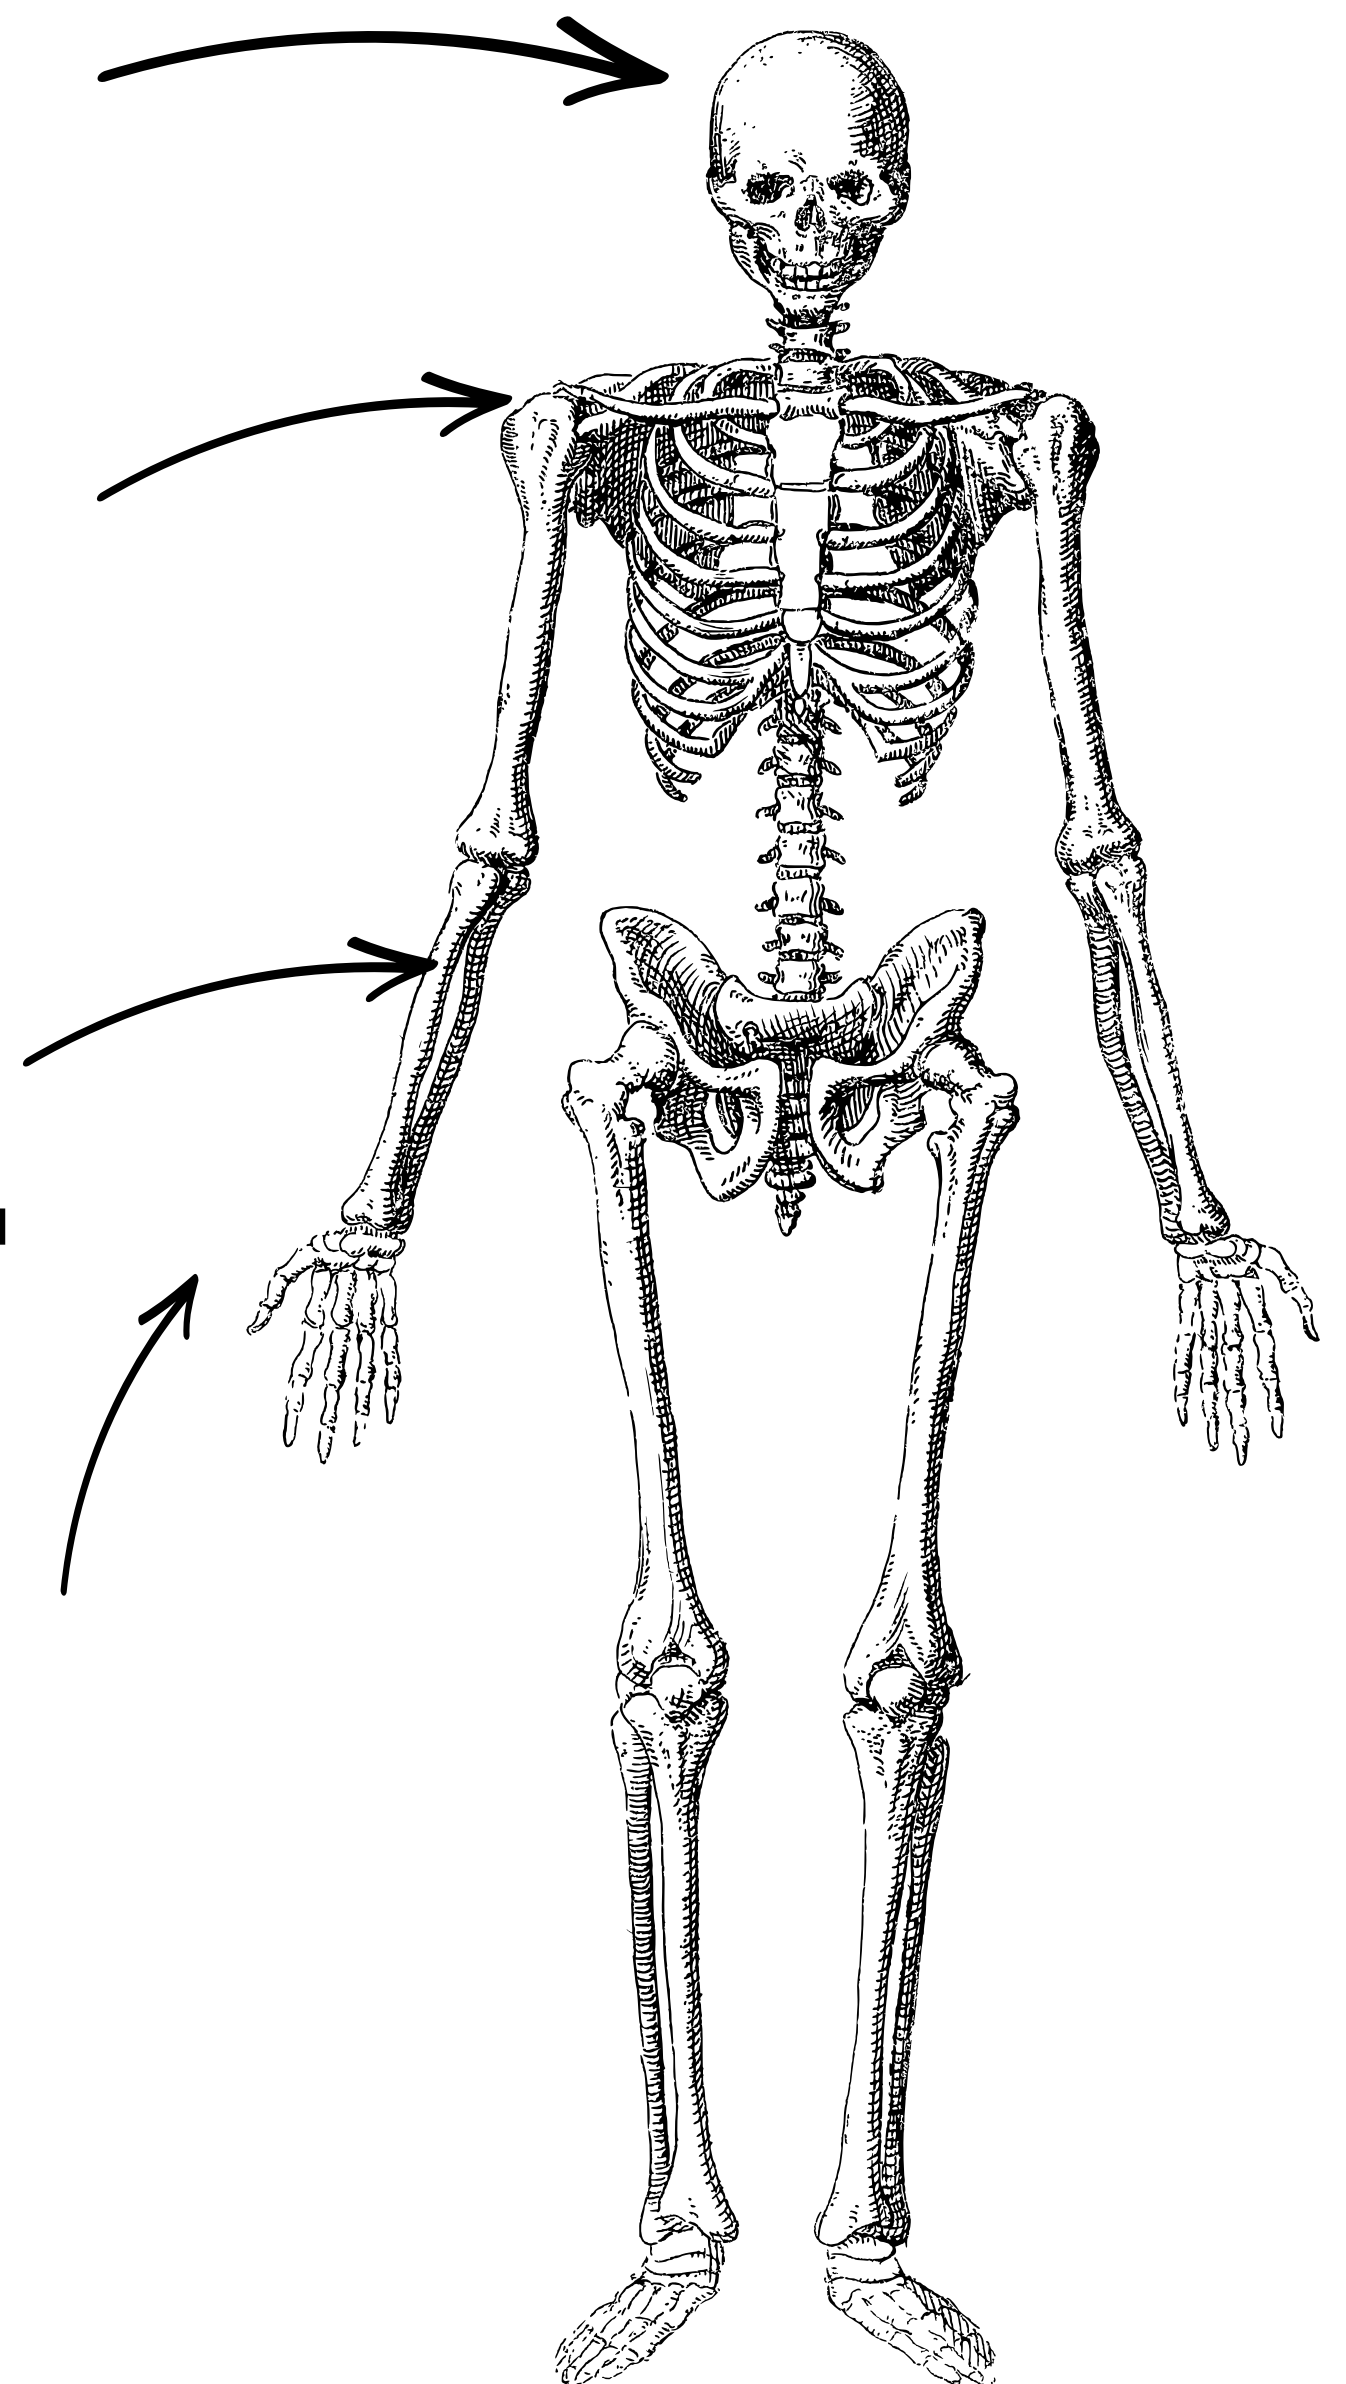

Types of BONES

Cranium: The cranium acts as a rigid, durable helmet, shielding the delicate brain and brainstem from physical injury.

Collar Bone: it acts as a horizontal strut that holds your shoulder out and away from your chest so your arms can swing freely.

Long bone: A long bone is a dense, hard bone that provides strength, structure, and mobility. It is defined by being longer than it is wide and having a hollow central shaft.

Short bone: A short bone is a cube-like bone that is roughly equal in length, width, and thickness. It consists of a thin outer layer of compact bone covering a spongy, marrow-filled interior.

Funtions of THE BONES

Our bones support your body. They keep your body stable when you're not moving. And they help you move when you're active.

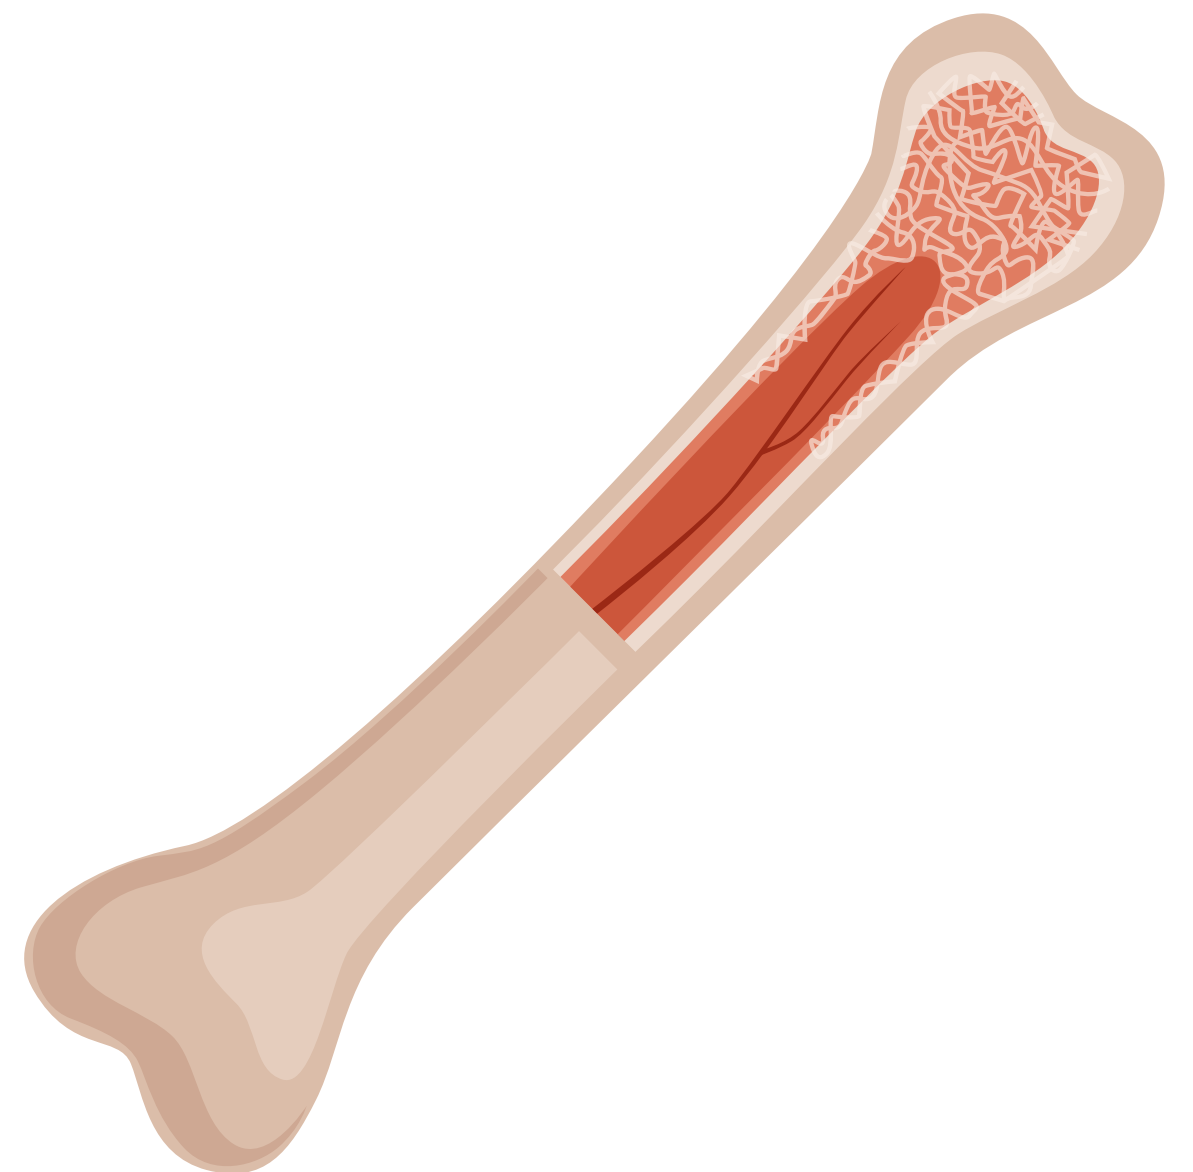

Bones secure and support lots of important tissue throughout your body. Think about the walls of your home again. Instead of holding drywall, plumbing and wiring in place, your bones are connected to a lot of tissue. Examples include:

- Muscles
- Nerves
- Tendons
- Ligaments

Some bones protect your internal organs. For example, your skull guards your brain. And your ribcage shields your heart, lungs and other organs near your chest.

Bones contain and protect your bone marrow. Bone marrow is a soft, fatty tissue that produces important cells, like:

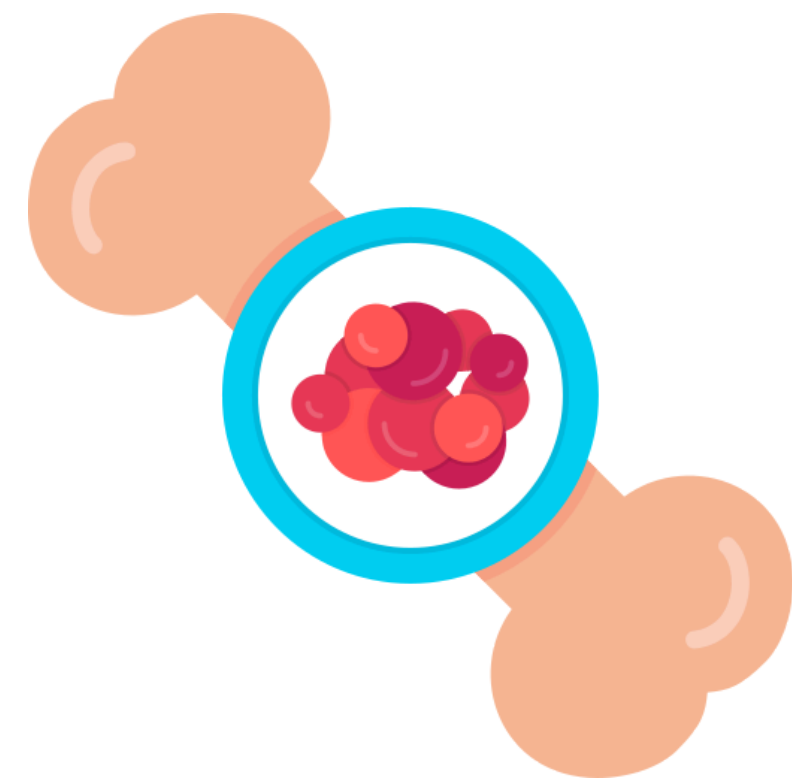

- Red blood cells
- White blood cells

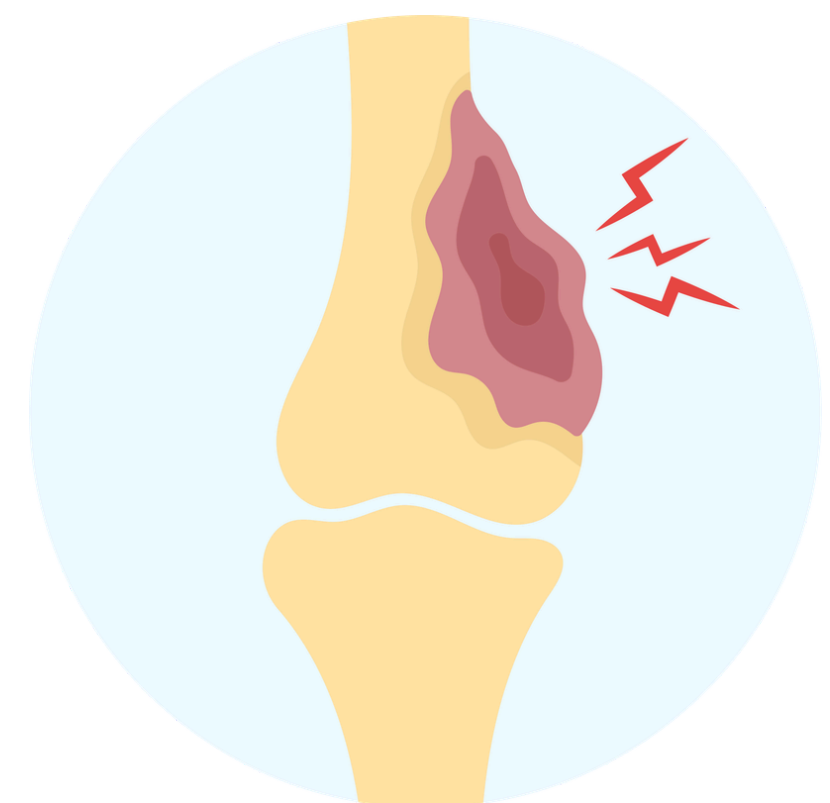

Disease

Bone Cancer: Bone cancer is cancer that begins in or spreads to your bones. Bone cancer can grow in any of the more than 200 bones in your body, although some bones are affected more commonly than others. Bone cancer can affect both adults and children.

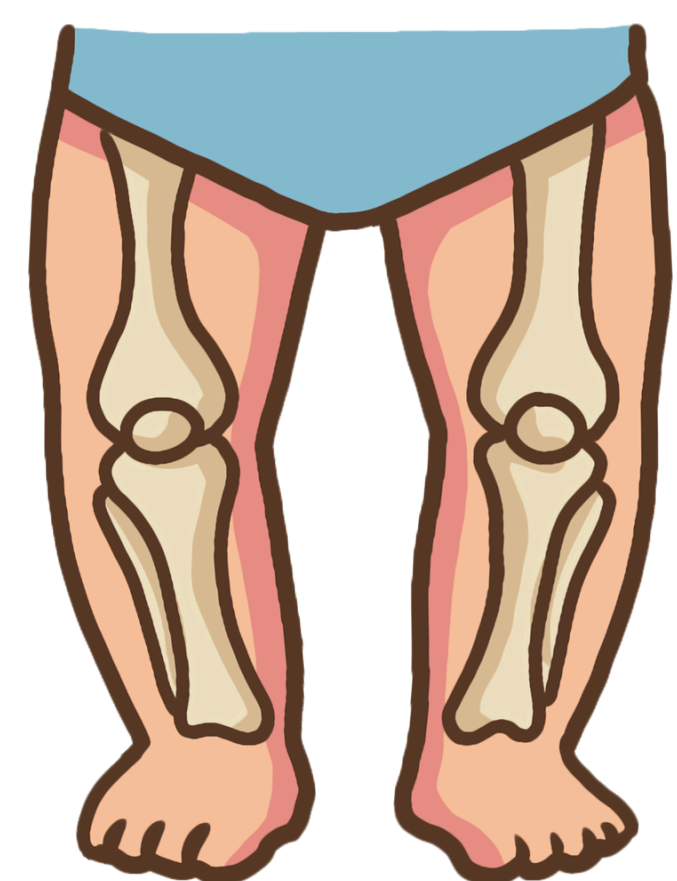

Osteomyelitis: is an infection of the bone. Any bone can be affected, but it is most common in arm and leg bones in children, and in the foot, back and pelvis bones in adults. Early treatment reduces the chance of permanent bone damage.

Rickets: is a bone disease that causes your bones to be soft and weak. It can be prevented with a good diet and some exposure to sunlight for vitamin D.

Rickets occurs in children, and occasionally teenagers. It does not occur in adults, as it only affects growing bones. Rickets is not common in Australia.

Fun facts

Fun Facts

Adults have between 206 and 213 bones.
Babies are usually born with 270 bones that
grow together and fuse into their adult
skeletons.

Babies have about 100 more bones than adults.

The enamel in your teeth are stronger than any
other bone in your body.

Your skeleton is replaced roughly every seven
years.

More than half your bones are in your hands
and feet.

Kneecaps aren't fully developed until age 10 to
12.
